<sup>131</sup>I <467 µBq m<sup>-3</sup>

anta@physics.auth.gr

IAEA CN-235, Vienna Austria

## <sup>131</sup>**I**, <sup>137</sup>**Cs** and <sup>134</sup>**Cs** in air

#### <sup>131</sup>I <500 µBq m<sup>-3</sup>

The maximum <sup>131</sup>I activity concentration observed in Milan, Italy was almost similar with the highest value (497  $\mu$ Bq m<sup>-3</sup>) observed in Thessaloniki, Greece, and the highest observed value (490  $\mu$ Bq m<sup>-3</sup>) in Athens Greece but was lower than the one observed (810  $\mu$ Bq m<sup>-3</sup>) in Svalbard [Paatero et al., 2012] and in Lithuania (3700  $\mu$ Bq m<sup>-3</sup>, [Lujaniene et al., 2012]).

#### <sup>137</sup>Cs <63 µBq m<sup>-3</sup>

The max <sup>137</sup>Cs activity concentration at Milan, Italy was 63  $\mu$ Bq m<sup>-3</sup>, while in Thessaloniki, Greece was 145  $\mu$ Bq m<sup>-3</sup> and in Svalbard as high as 675  $\mu$ Bq m<sup>-3</sup>.

In most sampling sites is measured only the fraction of <sup>131</sup>I bound to aerosol particles.

The ratio value of of gaseous to total <sup>131</sup>I equal to 0.79, according to measurements in Athens (Potiriadis et al., 2011).

Masson et al. (2011) reported that measurements taken near Fukushima showed that the average ratio of gaseous to total <sup>131</sup>I was around 0.71, while European measurements showed an average gaseous to total <sup>131</sup>I ratio of 0.77.

#### <sup>134</sup>Cs/<sup>137</sup>Cs activity ratio = 1

![](_page_10_Figure_1.jpeg)

Fukushima fallout isotopes at Thessaloniki

<sup>134</sup>Cs/<sup>137</sup>Cs =1

Related to the burn-up history of the nuclear fuel of the destroyed nuclear reactor.

According to Kirchner et al. (2012) the isotopic compositions observed in Europe correspond to emissions from units 1 and 3 of the destroyed Fukushima reactor.

For comparison after the Chernobyl accident the ratio was about 0.5

IAEA CN-235, Vienna Austria

# <sup>131</sup>I/<sup>137</sup>Cs activity ratio

#### <sup>131</sup>I/<sup>137</sup>Cs activity ratio in Milan (45°) and Thessaloniki (40°)

![](_page_11_Figure_2.jpeg)

#### <sup>131</sup>I/<sup>137</sup>Cs decreases with time

The high <sup>131</sup>I/<sup>137</sup>Cs ratio, observed during the first days after the accident, followed by lower values later on, reflects not only the initial release ratio but also differences in volatility, attachment and removal of two isotopes during transportation due to their different physico-chemical properties.

The presence of more than one peak of <sup>131</sup>I and <sup>137</sup>Cs could indicate "fresh" air masses that arrive from Fukushima in both regions up to the end of April/first days of May.

## <sup>131</sup>I atmospheric concentrations

![](_page_12_Figure_1.jpeg)

#### <sup>131</sup>I maximum 3-4 April ~500 μBq m<sup>-3</sup>

Similar maximum values have been observed during 3-4 April, 2011 in both regions, despite the considerable distance and the possible differences of climatic parameters that may influence the air concentrations of nuclides. But in general, there is a

shift trend in the peak days.

NOAA HYSPLIT MODEL Backward trajectories ending at 1300 UTC 26 Mar 11 GDAS Meteorological Data

![](_page_13_Figure_2.jpeg)

The NOAA HYSPLIT model was used to assess the transport pattern and to explain the deviation in radionuclide activity concentrations found.

Thirteen days (312) back trajectories were calculated for different arrival height and for 12 UTC time.

The trajectories are labeled every 24h by a filled symbol.

NOAA HYSPLIT MODEL Backward trajectories ending at 1300 UTC 26 Mar 11 GDAS Meteorological Data

![](_page_14_Figure_2.jpeg)

The first maximum in concentration of <sup>131</sup>I (332 µBq m<sup>-3</sup>) was observed at Thessaloniki on **26th of March** 2011.

Air masses were lifted rapidly and transported over the North America to Europe at height of 500 m.

Air masses were also traveled at higher atmosphere levels from Japan. It is also possible that radioactive particles were transported at higher altitudes and may have been removed in the lower layer of the atmosphere due to various reasons, e.g. rainfall characteristics, fog formation or growth of aerosol particles and their deposition.

anta@physics.auth.gr

NOAA HYSPLIT MODEL Backward trajectories ending at 1200 UTC 07 Apr 11 GDAS Meteorological Data

![](_page_15_Figure_2.jpeg)

An example of transported air mass at **07 of April 2011** at Milan, Italy is presented.

The results showed a direct transfer from Fukushima across the Pacific Ocean, a transport through the North Pole and a pathway through the Greenland and Iceland at height of 500 m to Milano.

The air masses at higher altitudes were rapidly transported, while the air masses at 500 m exhibited rather slow transport.

NOAA HYSPLIT MODEL Backward trajectories ending at 1200 UTC 07 Apr 11 GDAS Meteorological Data

![](_page_16_Figure_2.jpeg)

Although the second maximum of concentration of <sup>131</sup>I that observed at Milan on 7th of April can be attributed to the advection of air masses from Japan at altitude of 500 m, however, the back-trajectory analysis for the same day at Thessaloniki indicates no transport of air masses from Japan, at least for height of 500 and 1500 m.

NOAA HYSPLIT MODEL Backward trajectories ending at 0000 UTC 10 Apr 11 **GDAS** Meteorological Data ш 6 22 40.50 N at ⊀ Source Meters AGL 8000 6000 4000 2000 00 00 00 00 00 00 00 00 00 00 00 00 00 04/0904/0804/0704/0604/0504/0404/0304/0204/0103/3103/3003/2903/28 This is not a NOAA product. It was produced by a web user. Job ID: 333310 Job Start: Sun Feb 19 13:39:26 UTC 2012 Source 1 lat.: 40.5 Ion.: 22.9 hgts: 500, 3000, 5000 m AGL Trajectory Direction: Backward Duration: 312 hrs Vertical Motion Calculation Method: Isentropic Meteorology: 0000Z 08 Apr 2011 - GDAS1

On 10th of April back-trajectory analysis showed a direct transfer from Fukushima across the Pacific Ocean, a transport through the North Pole and a pathway through the Greenland and Iceland to Thessaloniki.

The air masses on that day reach Thessaloniki from Northwest direction and this is possible the reason why no maximum concentration was observed at Milan.

#### Dose assessment

The limit of the effective dose for the population is fixed for the Italian Low of Radioprotection in 1 mSv y<sup>-1</sup> (Italian Government Legislative Decree, 1995).

The evaluation of the effective dose is done by the relation:

$$E = E_{est} + \sum_{j} h(g)_{j,ing} J_{j,ing} + \sum_{j} h(g)_{j,inh} J_{j,inh} < 1 \text{ mSv } a^{-1}$$

where, E<sub>est</sub> is the effective dose for exposure; Jj,<sub>ing</sub> and Jj,<sub>inh</sub> are the intake activity (Bq) by ingestion and by inhalation of radionuclide j, respectively;

 $h(g)_{j, ing}$ ,  $h(g)_{j, inh}$  (Sv Bq<sup>-1</sup>) are the coefficients of committed dose for unit of intake by ingestion and/or by inhalation for the population of age group g, due to radionuclide j.

#### Dose assessment

Coefficients of committed dose for unit of intake by ingestion and/or by inhalation for the population of age group g, for the radionuclides of interest, per unit of intake – Sv Bq<sup>-1</sup>

Nuclide	age < 1 a $h(g)_{ing}$	age > 17 a h(g) <sub>ing</sub>	$age < 1 \; a^{(*)} \ { m h(g)} \;_{inh}$	$age > 17 a^{(*)}$ h(g) <sub>inh</sub>
I-131	1,8 10 <sup>-7</sup>	2,2 10 <sup>-8</sup>	7,2 10 <sup>-8</sup>	7,4 10 <sup>-9</sup>
Cs-137	$2,1 \ 10^{-8}$	1,3 10 <sup>-8</sup>	8,8 10 <sup>-9</sup>	4,6 10 <sup>-9</sup>
Cs-134	2,6 10 <sup>-8</sup>	1,9 10 <sup>-8</sup>	1,1 10 <sup>-8</sup>	6,6 10 <sup>-9</sup>
			(*) ד	

<sup>(\*)</sup> Fast Type of Absorption

Annual individual usage factors for external exposure, inhalation and consumption of foods. reported in NCRP-123 publication

Pathways - External and Inhalation	Unit	Exposure
Inhalation	$m^3 a^{-1}$	8 000
Pathways - Ingestion	Unit	Intake
Water and beverages	$L a^{-1}$	800
Milk	$L a^{-1}$	300

#### Dose assessment

The evaluation of the Effective Dose was done using the highest concentration value for  $^{131}I$ ,  $^{134}Cs$  and  $^{137}Cs$  measured (Tables 1, 2, 7), and are taken into account only the h(g) coefficients for population of age less than 1 year old and greater than 17 a.

## CONCLUSIONS

- The Fukushima plume was detected in Milan, Italy and Thessaloniki, Greece
- > HYSPLIT backward trajectories interpreted the measured atmospheric concentrations
- The relative high concentrations of <sup>137</sup>Cs in grass, soil and fresh milk samples, correspond to Chernobyl fallout
- <sup>131</sup>I and <sup>137,134</sup>Cs isotopes were found above their detection limits in all environmental samples but very far below levels of concern
