The Agency's Statute was approved on 23 October 1956 by the Conference on the Statute of the IAEA held at United Nations Headquarters, New York; it entered into force on 29 July 1957. The Headquarters of the Agency are situated in Vienna. Its principal objective is "to accelerate and enlarge the contribution of atomic energy to peace, health and prosperity throughout the world".

## FOREWORD

This report is the thirty-sixth in the Agency's series of annual reports on operating experience with nuclear power stations in Member States.

As in previous years, in addition to annual performance data and outage information, the report contains a historical summary of performance and outages during the lifetime of individual plants and five figures illustrating worldwide performance and statistical data.

It is hoped that this report and related Agency publications will be useful to everyone concerned with nuclear power reactors. Suggestions and corrections from readers would be most welcome.

# 1. INTRODUCTION

This report is the thirty-sixth in the Agency's series of annual reports on operating experience with nuclear power stations in Member States.

The report is a direct output from the Agency's Power Reactor Information System (PRIS), whose databank contains all operating experience data published in the Agency's operating experience annual reports since 1971 and basic information on power reactors, including design data. It presents operating experience data for all worldwide nuclear power plants after starting commercial operation. The PRIS databank is available free of charge to IAEA Member States through its two services: PRIS-PC, and PRIS CD-ROM. The PRIS-PC allows direct access to the database through the Internet. The PRIS-PC on CD-ROM only includes data for reactors in operation, under construction and shutdown. It keeps the same feature as in the current front-end-tool PRIS-PC interface. This front-end-tool interface allows to search and query through pre-designed statistics. The PRIS-PC on CD-ROM contains mapping interface including a view of the world map with zooming features to country, region and site map and links to PRIS database to retrieve related (nuclear power plant) information. PRIS data and related indicators are also available on the PRIS Website: [www.iaea.org/programmes/a2](http://www.iaea.org/programmes/a2). It contains publicly available information about reactor units and nuclear industry results.

Load, operation and availability factors are used as the basic performance indicators. Energy unavailability factors, separate for planned and unplanned unavailability, due either to causes under plant management control or external causes out of plant management control, are used as a measure of energy lost through a unit not being available. However, some ambiguity remains in the operators' reports of the unavailability data, resulting in inconsistencies in these factors. It is recognized that there is an inherent difficulty in reporting unavailability in energy due to external causes with relation to energy losses due to load following operation and grid limitation. It should be noted that, for load, operation and unavailability factors, there might be differences between the data of this report and those published elsewhere. To avoid confusion, reference should be made to the definitions given in Section 3. In Section 4 this report presents figures illustrating worldwide performance indicators up to 2004.

According to the information available to the Agency at the end of 2004, there were 440 nuclear power reactors operating in the world, with a total net capacity of 366.3 GW<sub>(e)</sub>.

Five new reactor units were connected to the grid in 2004 (two in Ukraine and one each in China, Japan and the Russian Federation), and one laid-up plant was reconnected in Canada. This compares to two new grid connections and two reconnections in 2003.

There were five NPP retirements in 2004 — four 50 MW(e) units in the United Kingdom and the 1185 MW(e) Ignalina-1 reactor in Lithuania. This compares to six retirements in 2003.

At the end of 2004 there were 26 nuclear power plants under construction in the world with a total net capacity 20.8 GW<sub>(e)</sub>. Construction began on two NPPs in 2004, India's 500 MW(e) prototype fast breeder reactor and Japan's 866 MW(e) Tomari-3 PWR. In addition, active construction resumed on two NPPs in the Russian Federation, Kalinin-4 and Balakovo-5.

The information contained in the report was made available to the Agency through designated national correspondents and the US Nuclear Regulatory Commission (NRC) and Department of Energy (DOE).

The Agency appreciates the valuable assistance that it has obtained from the national authorities, official correspondents and various electrical utilities in gathering the information for this report.

This publication includes information received by the Agency up to 30 September 2004. Up to this date from 15 British units (operated by British Energy) and from 1 French unit (Phenix) had not been reported. Information received after that date, although not included in this publication, is available in the PRIS database.

The report was compiled by staff of the Agency's Division of Nuclear Power. It is hoped that it will be useful to nuclear power plant operators, nuclear system designers, nuclear power planners, interested professional engineers and scientists and others concerned with the operating experience with nuclear power reactors. Suggestions and corrections from readers would be most welcome.

### 3. DEFINITIONS

#### 1. Reference Unit Power - maximum electrical capacity, RUP [ $MW_{(e)}$ ]

The reference unit power is the maximum (electrical) power that could be maintained continuously throughout a prolonged period of operation under reference ambient conditions.

It is specified that this value must remain constant for a given unit unless, following permanent modification, or a new permanent authorization, the management decides to amend the original value.

The reference unit power may be gross of net:

– The gross RUP ( $P_g$ ,  $MW_{(e)}$ ) is deemed to be measured at the output terminals of all generator sets in the station; it includes therefore the power taken by the station auxiliaries and losses in transformers that are considered integral parts of the station.

– The net RUP ( $P_n$ ,  $MW_{(e)}$ ), indicating the maximum power that can be supplied, is measured at the station outlet terminals, i.e. after deducting the power taken by station auxiliaries and the losses in the transformers that are considered integral parts of the station.

#### 2. Design net capacity [ $MW_{(e)}$ ]

The net reference unit power as specified in an original unit design.

#### 3. Reference period, T [hours]

For units in power ascension at the end of the period, the clock hours from the beginning of the period or the first electrical production, whichever comes last, to the end of the period.

For units in commercial operation at the end of the period, the clock hours from the beginning of the period or of commercial operation, whichever comes last, to the end of the period or permanent shutdown, whichever comes first.

#### 4. On-line hours, t [hours]

The total clock hours in the reference period during which the unit operated with breakers closed to the station bus.

#### 5. Reference Energy Generation, REG [ $MW_{(e)}h$ ]

Net electrical energy which would have been produced if the unit were operated continuously at the reference unit power during the whole reference period.

#### 6. Energy Generated (net), EG [ $GW_{(e)}h$ ]

Net electrical energy produced during the reference period as measured at the unit outlet terminals, i.e. after deducting the electrical energy taken by unit auxiliaries and the losses in transformers that are considered integral parts of the unit. If this quantity is less than zero, zero is reported.

## 7. Load Factor, LF [%]

$$LF = \frac{EG}{REG} \times 100$$

EG = energy generated (net), [MW<sub>(e)</sub>h]  
REG = reference energy generation [MW<sub>(e)</sub>h]

Load factor, for a given period, is the ratio of the energy, which the power unit has produced over that period, to the energy it would have produced at its reference power capacity over that period.

## 8. Operation factor, OF [%]

$$OF = \frac{t}{T} \times 100$$

t = number of hours on-line [h]  
T = number of hours in the reference period [h]

Operation factor is the ratio of the number of hours the unit was on-line, to the total number of hours in the reference period, expressed as a percentage. It is a measure of the unit time availability on the grid and does not depend on the operating power level.

## 9. Available capacity, P [MW<sub>(e)</sub>]

The available capacity at a given moment is the maximum net capacity at which the unit or station is able or is authorized to be operated at a continuous rating under the prevailing conditions assuming unlimited transmission facilities.

## 10. Energy loss, EL [MW<sub>(e)</sub>h]

Energy loss is the energy which could have been produced during the reference period by the unavailable capacity; it is categorized into three types:

- PEL - planned energy loss
- UEL - unplanned energy loss
- XEL - energy loss due to causes external to the plant

UEL comprise shutdowns, unplanned load reductions or outage extensions.

## 11. Unavailability

The unit unavailability is defined as a status when the plant is not able to operate at its maximum capacity (reference power). This condition, which may be under or beyond plant management control, should only reflect lack of availability of the plant itself, regardless of energy demand, transmission grid condition or political situation in the country.

Unavailability is classified as planned if it is foreseen at least 4 months in advance, generally at the time when the annual overhaul programme is established, and if the beginning of the unavailability period can be largely controlled and deferred by management. Unavailability is classified as unplanned if not scheduled at least four weeks in advance. Power plant operation at lower than maximum capacity because of lower demand from the grid but available to operate at the maximum capacity, does not constitute unavailability, either planned or unplanned.

## 12. Energy Availability Factor, EAF [%]

$$EAF = \frac{REG - PEL - UEL - XEL}{REG} \times 100$$

The energy availability factor over a specified period, is the ratio of the energy that the available capacity could have produced during this period, to the energy that the reference unit power could have produced during the same period.

## 13. Energy Unavailability Factor, EUF [%]

$$EUF = \frac{EL}{REG} \times 100$$

The unavailability factor over a specified period is the ratio of the energy losses EL that have not been produced during this period due to the unavailable capacity, to the energy that the reference unit power could have produced during the same period.

The energy unavailability factor EUF over a specified period can be divided into:

PUF = planned unavailability factor

UUF = unplanned unavailability factor due to causes in the plant

XUF = unplanned unavailability factor due to causes external to the plant.

The unavailability factor can be expressed as:  $EUF = 100 - EAF$

#### 14. Unit capability factor, UCF [%]

$$UCF = \frac{REG - PEL - UEL}{REG} \times 100$$

Unit capability factor is defined as the ratio of the energy that the unit was capable to generate over a given time period considering only limitation under the plant management control, to the reference energy generation over the same time period, expressed as a percentage. Both of these energy generation terms are determined relative to reference ambient conditions.

#### 15. Construction start

Date when first major placing of concrete, usually for the base mat of the reactor building, is done.

#### 16. First criticality

Date when the reactor is made critical for the first time.

#### 17. Grid connection

Date when the plant is first connected to the electrical grid for supply of power.

#### 18. Commercial operation

Date when the plant is handed over by the contractors to the owner and declared officially to be in commercial operation.

#### 19. Shutdown

Date when the plant is officially declared shut down by the owner and taken out of operation permanently.

#### 20. Outages

For the purpose of PRIS coding, the outage is defined as any status of a reactor unit, when its actual output power is lower than the reference unit power for a period of time. By this definition, the outage includes both power reduction and unit shutdown. The outage is considered significant, if the loss in the energy production corresponds to at least ten hours of continuous operation at the reference unit power or if it has been caused by an unplanned reactor scram (even if the unit had been shut down for less than 10 hours).

#### 21. Outage duration [h]

The total clock hours of the outage measured from the beginning of the reference period or the outage, whichever comes last, to the end of the reference period or the outage, whichever comes first.

**22. Factors** refer to the plants which were in commercial operation during the whole of the reference period.

**23. Cumulative factors** are given for the plants which were in commercial operation during full calendar years.

**24.** A blank and three periods (...), if used in tables, denote information that is not applicable or not available, respectively.

## **25. Types of outages**

The outage type is a three-character code. The third character is for unplanned outages only:

Code\_1 description:

- (U) Unplanned outage due to causes under the plant management control
- (X) Outage due to causes beyond the plant management control ("external")

- (2) Controlled shutdown or load reduction that had to be performed in the next 24 hours after the cause occurred
- (3) Extension of planned outage

| 01 Jan | 1236.0 | 1393.3  | PF   | C    | PERIODICAL INSPECTION AND REFUELLING.<br>THE REASON FOR THE FACTOR OF THE UNPLANNED ENERGY LOSS IS THAT THE GENERATOR WAS STOPPED AND REPAIRED BECAUSE THE AMOUNT OF REPLENISHMENT OF THE HYDROGEN GAS FOR COOLING THE GENERATOR INCREASED. AS A RESULT OF THE CHECK, THE CRACK OCCURED IN THE SOCKET WELD OF THE STATOR COOLING WATER SYSTEM PIPING IN THE GENERATOR. THE CAUSE WAS DUE TO THE THE POOR WELD AND THE VIBRATION WHILE DRIVING. |
