PLEASE BE AWARE THAT
ALL OF THE MISSING PAGES IN THIS DOCUMENT
WERE ORIGINALLY BLANK

The IAEA does not normally maintain stocks of reports in this series. However, microfiche copies of these reports can be obtained from

INIS Clearinghouse
International Atomic Energy Agency
Wagramerstrasse 5
P.O. Box 100
A-1400 Vienna, Austria

Orders should be accompanied by prepayment of Austrian Schillings 100,– in the form of a cheque or in the form of IAEA microfiche service coupons which may be ordered separately from the INIS Clearinghouse.

FOREWORD

The International Uranium Geology Information System (INTURGEO) is an international compilation of data on uranium deposits and occurrences. The purpose of INTURGEO is to provide a clearinghouse for uranium geological information that can serve for the better understanding of the worldwide distribution of uranium occurrences and deposits. In this way insights may be provided into the metallogeny of uranium, the identification of new prospective areas and regional resource appraisal. The INTURGEO system is by no means complete for all regions of the world. Data have been available principally from the World Outside Centrally Planned Economy Areas (WOCA).

INTURGEO currently covers 6,089 occurrences and deposits in 96 countries. Data on some 4,596 occurrences in 92 countries are presented in this volume. The information presented in this publication has been collected from literature and through questionnaires sent to IAEA Member States. The valuable co-operation of the Member States is greatly appreciated.

The initial work on INTURGEO was performed by Ms. L. Trocki and Mr. M.V. Hansen in 1979 within the Division of Nuclear Power and Reactors (TONP). The present database design and programming were performed by Mr. D.W. McCarn, from the Division of Nuclear Fuel Cycle (NENF), with programming assistance from Messrs. C. Okonkwa, M. Raatz and F. Varecka of the Computer Section, Division of Scientific Information (NESI). The database administrator was Mr. J. Russel, NESI. Data preparation was performed principally by Mr. D.W. McCarn and Ms. F. Saszedj with the co-operation of the staff of the Nuclear Materials and Fuel Cycle Technology Section, NENF. Data entry was performed by Ms. A. Magbojos and Ms. M. Marquart, NESI. The mapping package was developed by Mr. D.W. McCarn from the PLTSYM computer system published by the US Department of Energy [1]. Financial assistance for this project was received from the Federal Republic of Germany and the United States of America. Grateful appreciation is extended to the encouragement and support extended by Mr. J.A. Patterson, NENF.

EDITORIAL NOTE

In preparing this material for the press, staff of the International Atomic Energy Agency have mounted and paginated the original manuscripts and given some attention to presentation.

The views expressed do not necessarily reflect those of the governments of the Member States or organizations under whose auspices the manuscripts were produced.

The use in this book of particular designations of countries or territories does not imply any judgement by the publisher, the IAEA, as to the legal status of such countries or territories, of their authorities and institutions or of the delimitation of their boundaries.

The mention of specific companies or of their products or brand names does not imply any endorsement or recommendation on the part of the IAEA.

INTRODUCTION

The International Uranium Geology Information System (INTURGEO) is an international compilation of data on uranium deposits and occurrences. The purpose of INTURGEO is to provide a clearinghouse for uranium geological information that can serve for the better understanding of the worldwide distribution of uranium occurrences and deposits. In this way insights may be provided into the metallogeny of uranium, the identification of new prospective areas and regional resource appraisal. The INTURGEO system is by no means complete for all regions of the world. Data have been available principally from the WOCA countries.

INTURGEO currently covers 6,089 occurrences and deposits in 96 countries of which 4,596 occurrences in 92 countries are presented here. The information presented in this publication is a very brief, one line synopsis of deposits and occurrences, and has been collected from literature and through questionnaires sent directly to IAEA Member States. None of the information contained in the INTURGEO database was derived from confidential sources although there are many entries which come from the internal files of Member States and are not directly available in the general literature. The uniformity of the INTURGEO data presented in this report has depended heavilly on the data provided by Member States. In some cases, the data quality was extremely good and an exhaustive effort was made to present a complete picture of uranium occurrences and deposits. In other cases, response to questionnaires was qualified and the resulting data incomplete. It is hoped that the information contained in the INTURGEO system will also be of benefit to geologists and explorationists working on other commodities and other geological problems.

It should be noted that much of the information gathered on deposits and occurrences is not of current economic interest. A decision was made early in the programme to include what was available in the literature and other sources because more information is needed than the current economic ore deposits to fully define the nature of uranium distribution in the world.

It was impossible for the data recorders to judge the value of much of the data. The actual process of data selection required much more time

than the recording of the data. Where contradictory information was available, decisions whad to be made regarding its validity. Often, the same occurrence or deposit had multiple names recorded in the literature. An example was with the Osamu Utsumi mine in Brazil. This deposit has been reported in the literature as Pocos de Caldas, Minas de Caldas and Cercado to name a few synonyms. Hopefully, most instances of duplicate reporting have been recognized and corrected. The uranium occurrences and deposits contained in this volume have been recorded individually deposit and occurrence.

Although a small occurrence may be insignificant in itself, the overall pattern of uranium occurrences might provide important clues to regional metallogeny. An a priori decision not to record the smaller occurrences would prevent regional interpretation of the data and reduce its usefulness for recognizing promising new uranium areas.

Data in the Atlas

The objective of the INTURGEO Atlas is to provide in one source basic data on uranium occurrences and deposits throughout the world. This basic information includes the deposit or occurrence name, the mining district, the tectonic setting, the geological type, status, size, host-rock type, age of mineralization and bibliographic references.

The Atlas does not include detailed descriptive information on each entry. These data will be made available through computer media. The data contained in the maps of the atlas include all reported occurrences of uranium above the anomaly level. Data, including that at anomaly level supplied by Member States, is reported in the tables. Anomaly data reported in the literature are not included. The categories of occurrence and deposit status includes:

Anomaly
Occurrences of Unknown Status
Occurrences
Prospects
Developed Prospects
Subeconomic Deposits
Economic Deposits

Mines

Inactive Mines

Depleted Mines

Countries were not included in this volume where the overall level of information was not adequate to be representative of the country. In other cases, information is provided in the tables but not on maps because the location is inadequate. In this case, the map-number is suffixed with a star, "*", to identify occurrences and deposits not presented on maps.

Availability of INTURGEO Data

Much detailed information has been recorded in INTURGEO. Most of this detail is in the form of text comments describing the geology of the deposits or occurrences. This information is not included in this volume but is available on magnetic tape, computer-generated microfische, and by custom retrievals. A microcomputer version of INTURGEO on 21 Megabyte Bernoulli disks is available. Refer to the discussion on page 15 of the INTURGEO/MicroISIS system for details. Because the total volume of information amounts to about 10,000 pages of text and descriptions the data cannot be made available except through computer or microfische media.

Requests for INTURGEO data and services may be may through:

Director, Division of Nuclear Fuel Cycle
International Atomic Energy Agency
P.O. Box 100
A-1400 Vienna
AUSTRIA

Organization of the Tables

The Tables for the Atlas of uranium occurrences and deposits are divided into three parts, based on the sources of information. Since the information gathered from Canada and the United States of America was provided in different formats than the data for the rest of the world, these two countries are listed separately. All deposits and occurrences

are listed according to an assigned map code described below. Abbreviation for rock names, geological terms and ages are listed in Annex I. Rock name abbreviations were abstracted from mnemonic codes developed by the Geological Survey of Canada [2].

Oganization of the Maps

The maps in the Atlas are organized hierarchically. For each continent, there is a synoptic map showing the distribution of all uranium occurrences at the scale of 1:20,000,000 to 1:40,000,000. Within this map, outlines of inset maps are included as necessary. These are at scales of 1:1,200,000, 1:3,000,000, 1:6,000,000 or 1:8,500,000. Annex II contains the list of included maps, their bounding coordinates and scales. Sometimes it has been necessary to provide an additional level of detail for districts. A map code associated with every occurrence and deposit is used to index the Atlas maps with the tables. The map code is composed of a two or three character country code and a numerical assession number (e.g. COL-005). Annex III contains all country codes, the country names used in the tables, the official country name and the number of records presented in the Atlas.

The maps also contain pie charts showing the deposit or occurrence types and status or size. Different symbols are used to define the deposit types on the maps and the size of that symbol shows the deposit status or size.

Geological Classification

The geological classification scheme used for deposits and occurrences outside the United States of America is based on the deposit types used by the NEA-IAEA [3] but has been expanded to include metasomatic deposits, deposits in volcanic rocks, phosphorites and heavy mineral placers. This classification scheme is shown in Annex IV. For information from the United States of America, the classification scheme used by the U.S. Department of Energy (U.S. DOE) [4] is described in Annex V.

Sources of Information

Information for the INTURGEO project was collected primarily through the published literature, Agency internal files, unrestricted Agency Technical Co-operation reports, and directly from Member States via a questionnaire providing drafts for each country of the data entitled "INTURGEO Preliminary Country Report". Occasionally, data were obtained from debriefing of Agency experts for specific projects and from visiting scientists attending Agency meetings.

A large quantity of data was received from the United States of America which contained detailed descriptions of all uranium occurrences identified during the US Department of Energy's National Uranium Resources evaluation (NURE) programme. The data provided were the original data collection forms prepared by the project geologists. This source of information is collectively referenced to the NURE quadrangle folios.

For ease of use, the bibliographic references used in the INTURGEO database are listed both numerically and alphabetically in Tables 4 and 5 of Part I of the Atlas.

Accuracy of the Information

Every effort has been made to provide a complete coverage throughout the world, but given the magnitude of the task and the problems involved in data verification, it is not yet complete. Further improvement of the INTURGEO database will depend on the careful checking and review by Member States of the current information in the system.

The accuracy of the information contained in this Atlas is determined to a large degree on the active participation of the Member States in the careful checking and review of the INTURGEO Preliminary Country Reports as well as the preparation of new occurrences and deposits for entry into the INTURGEO database. Better uniformity of data can only be achieved by the active commitment by all Member States in the complete review of the available data. There is a bias introduced by the Member States on the database depending on the how the questionnare was answered. These biases are reflected in the distribution of occurrences and deposits in the present report.

A Note on the Mapping Package

The mapping package used in the preparation of the World Atlas was modified from the PLTSYM mapping package developed by Bendix Field Engineering Corporation in Grand Junction, Colorado and published by the U.S.DOE [1]. The programs were modified to permit the projection of maps in the southern and eastern hemispheres and to provide for country outlines, legends and different symbols for deposit types. Additionally, capability for pie diagrams of the data was added.

Additionally, plotting subroutines compatible with the CALCOMP standards were developed using the GDDM (Graphical Data Display Manager) system on the IBM mainframe. These subroutines permit the maps plotted on the hardcopy plotter to be viewed and edited on a 3279 graphics diplay terminal. Without this facility, the preparation of Atlas maps would have been impossible.

The maps were plotted on a Benson-Varian model 9211 plotter which has a maximum y-dimension size of 10.5 inches (26.7 cm). For this reason, the maps produced for the Atlas are either A3 or A4 format.

The country outlines were derived from Agency SAS (Statistical Analysis System) datasets. The SAS/GRAPH package [5] was unable to provide sufficient quality for the Atlas thus requiring the development of the PLTSYM programs. It should be emphasized that the country outlines presented do not reflect Agency position regarding international boundaries.

DATABASE MANAGEMENT CONSIDERATIONS

Introduction

This section describes the database management techniques and systems used for the INTURGEO project. Two independent database management systems are currently in use and have different characteristics and philosophies of organization. The first, a highly structured hierarchical database system called ADABAS (Adaptable Data Base Management System) with fixed length fields was initially inplemented in 1981. Because of the evolving requirements for the system, this structure was soon modified to include significant amounts of text information.

As the requirements for a text oriented system became more sophisticated and direct retrievals based on text became desirable, a second text-oriented database was developed in 1984 for the data from the USA and has proven to be more accessible to the geologist. The Agency is expanding this text-oriented system to include all of the INTURGEO data and is in the process of converting from a mainframe to a microcomputer database system. The CDS/ISIS package (Computerized Documentation Service / Intergrated Set of Information Systems) developed by UNESCO was used for this phase.

Additionally, the text-oriented system has a potentially important application in the development of recognition criteria for uranium deposits. An Agency programme is currently underway to expand the IAEA-NEA classification scheme and to develop detailed recognition criteria for the defined deposit types using the INTURGEO system.

ADABAS Model

The INTURGEO system was developed initially using a hierarchical database model as shown in Annex VI. The file descriptions, data dictionary and database structure was recommended by an INTURGEO Consultants' Meeting in 1981 and implemented during the following one and a half years. The ADABAS database management system was used and programs were written in the NATURAL language to support INTURGEO system for a mainframe IBM-3081 environment. Experience gained in developing

this model was used to design a similar database model for the CNEN in Brazil in 1983. Since that time, India has also developed a parallel database "INDURGEO" utilizing a network structure to permit the exchange of comparable data.[6]

ADABAS is a commercial database management system produced by Software A.G. of Darmstadt, Federal Republic of Germany. It is a "partially inverted list" type of generalized data management system and databases can be implemented with hierarchical, network or relational structure. The ADABAS system runs on a mainframe IBM environment, supports multiple users and is available both as an on-line or batch system. NATURAL is a generalized query and report-writing language which supports the ADABAS system [7,8]. For further information contact the Database Coordinator, Computer Section, Division of Scientific and Technical Information, IAEA.

ADABAS File Design

File design was developed by the use of third-normal form (TNF) analysis. This technique involves explicitly defining all file relations, relation keys, repeating fields and repeating groups. The recommended data fields were reviewed and reorganized to best reflect the anticipated database needs and a TNF analysis was performed. The resulting file structures were checked to see if the anticipated queries could easily be made and if the resulting data structures fitted geological data organization. Reporting forms were developed to check field lengths and to reflect the file structure. After minor reorganization the resulting data structures were "collapsed" into ADABAS files.

As the ADABAS file design was developed, redundant country names were included to eliminate the need to search other files in the file structure during retrievals by country name. Also, to prevent the need for many code tables, fields were not encoded but retained as text. Two unique keys were used in the accession of records. These are the deposit name, and a unique map-code assigned to each record for the convienience of preparing the Atlas maps.

Limitations of ADABAS Implementation

The ADABAS model as implemented by the IAEA suffered from three important problems that deserve serious consideration.

1. First, a file structure involving fields of fixed length for much of the data cannot convey the same scope and depth of geological meaning as simple text. This forces a type of decision making on the data recorder which (is difficult to recover from: making single-word conclusions about complex geological processes. In order to reduce this effect, considerable stress was placed on recording text information to supplement and expand on the original ADABAS model.

2. The second problem with the initial model of INTURGEO was that it permitted no convienient way for "Key-Word-In-Context" (KWIC) retrievals of text information. The ADABAS database management system does not, at the present time, permit the full inversion of text and the automated search of text information.

3. The third problem was the lack of programmer manpower required to support a complex file structure in ADABAS and NATURAL.

As a result of the first problem, the questionnaire developed for distribution to Member States was limited in scope compared to the original database design recommendations. Although frequently not effectively used, the questionnaire sought text information to supplement the "condensed" deposit/occurrence descriptions. Every attempt was made to provide partially completed forms for review and checking by Member States. These forms were transmitted to Member States as the "INTURGEO Preliminary Country Report". The response to this type of questionnaire and check list was exceptionally good for those countries queried in Asia, Africa and Latin America. An example of a Uranium Occurrence Report prepared for this questionnaire is in Annex VII.

KWIC Text-Oriented Database Model Using CDS/ISIS

In order to evaluate the effectiveness of an alternative philosophy in INTURGEO database management, and especially to solve problems noted above, a test was made using data supplied from the U.S. National Uranium

Resource Evaluation (NURE) programme by the U.S.DOE. During the NURE programme, a resource evaluation of 152 1°x 2° quadrangles resulted in the detailed description of uranium occurrences and deposits encountered in each quadrangle. Each Uranium Occurrence Report (UOR) was encoded on a data entry form six pages in length. Although never implemented as a computer system by the U.S.DOE, the original forms were provided to the Agency for processing. Several hundred partially completed UORs were received in computer readable form for NURE quadrangles evaluated by the U.S. Geological Survey. Altogether, 3389 uranium occurrence or deposit description were recorded including full text of all UORs in the NURE programme. The volume of information is about 5,000 pages of text descriptions.

The database management system chosen for this test was the CDS/ISIS package (Computerized Documentation Service / Intergrated Set of Information Systems) developed by UNESCO [9]. CDS/ISIS is a generalized data management system permitting the full inversion of text information. CDS/ISIS is available to Member States upon request from UNESCO and runs in a IBM mainframe environment with a VS or MVS operating system and using CICS (Customer Information Control System). A minicomputer version of CDS/ISIS is available for the HP 3000. A microcomputer version of CDS/ISIS (called CDS/MicroISIS) is available for the IBM PC-XT/AT, Wang PC, Olivetti M24 and the DEC PDP-11.

INTURGEO/MicroISIS Turn-Key System

A turn-key, microcomputer version of INTURGEO is available from the IAEA for IBM-PC compatible computers and utilizes CDS/MicroISIS. The system will be distributed as a 20 Mbyte Bernoulli disk in two volumes: The United States (Vol. 1) and The World Outside the United States (Vol. 2). The turn-key system contains search, display, data-entry, editing, standard report writers and software enabling the user to modify or change the basic system to fit his own needs.

Hardware configuration required for the turn-key INTURGEO syst an IBM-PC/XT, AT or compatible, 640 Kbyte RAM, 10 Mbyte Winchester 20 Mbyte Bernoulli box, 360 Kbyte 5.25" Diskette drive, 8087 Co CGA Adapter, colour monitor, and a printer.

INTURGEO/ISIS File Design

The design of the UOR data capture form developed for the NURE quadrangle programme (Annex VIII) directed the design of the CDS/ISIS database (Annex IX) and an example of a UOR from the CDS/ISIS system is presented in Annex X. The database design followed as closely as possible the USGS Computerized Resource Information Bank (CRIB) standards developed for the NURE UOR data form. These CRIB standards are reflected in other database designs by the U.S. Geological Survey notably the GS MRDS (Mineral Resource Data System) using dBASE III [10] released in August 1986. Hopefully, the maintenance of parallel standards in these types of geological databases will ease problems in the exchange of data.

Programming considerations were minimal compared to the ADABAS/NATURAL model and on-line data entry and KWIC searches proved to be much more efficient. One limitation of the CDS/ISIS system compared to ADABAS/NATURAL was that global manipulation of individual data fields is more cumbersome than with the ADABAS model. An advantage of CDS/ISIS compared to ADABAS was that field descriptions could be easily modified or added by the user without requesting changes through a database coordinator. CDS/ISIS is in this way more flexible from the users' point of view, but there are advantages in a controlled environment with secure backup as with ADABAS. Data security was maintained on the CDS/ISIS system through user-controlled automatic backups on a weekly basis. It was felt that the advantages gained by the CDS/ISIS system outweighted the disadvantages especially in view of how geologists ask questions of a database and recorder bias.

CDS/ISIS Limitations

One "built-in" problem with a text-oriented database using straight forward English syntax is associated with the efficient and effective ways to interrogate the database. With CDS/ISIS, KWIC searching is done using three Boolean operators (AND, OR and NOT) and an associative operator (parentheses). Also, CDS/ISIS has a "proximity" operator allowing the search of multiple word patterns and "right truncation" operator allowing the search for text beginning with a root term. Additionally, searching may be done selectively at the record or individual field level.

The problems associated with free text KWIC retrievals require the geologist to fully understand the semantic implications of various search strategies. Iterative refinement of a search strategy is the rule in a text-oriented database. This problem of search strategy is roughly the opposite of the problem #1 listed above in the ADABAS database model. There, the data recorder was required to make a decision concerning the geological meaning of a text description and express that concept in single word concepts. In the text-oriented database, no such prior decision is required although more consideration and judgement are required to achieve an appropriate retrieval using single-word concepts. This solution, however, is more acceptable than restricting search possibilities by the data recorder and imposing an unrecoverable operator bias.

Conclusions

Through the experience gained in both the ADABAS database model and the text-oriented CDS/ISIS model, especially as it relates to text-oriented deposit descriptions, the CDS/ISIS model most closely meets the requirements not only of the data but also of the geologist's use of the data. Adherence to existing database standards such as CRIB should permit the exchange of comparable information between Member States.

It is especially important to note that the text-oriented model does not create the operator bias by the data recorder implicit in the ADABAS model. This is not to say that the ADABAS model is without value, especially since it is accompanied with a powerful retreival language such as NATURAL. Rather, because of the nature of geological data, it is very difficult to precisely define data categories and therefore to define a valid data dictionary of database fields.

DESCRIPTION OF THE TABLES

Introduction

Information contained in this atlas has been divided into three parts depending on the origin of the data. These are: The World except for Canada and the United States of America (Table I), Canada (Table II), and The United States of America (Table III). Additionally, bibliographic references for these tables is contained in Table IV, sorted by reference number and Table V, sorted by author and date. Tables I-III differ according to the definitions of deposit type, status and descriptive information. These definitions are provided with the discussions of each table.

TABLE 1 Uranium Occurrences in the World Except Canada and the United States of America

The information contained in this table was gathered primarilly through Agency internal documents, published literature and questionnaires sent directly to Member States.

Data Field	Explanation
MAP-CODE	The map-code is a seven digit code prefixed by "CAN-" and followed by a three digit ascession number (e.g. CAN-123).
DEPOSIT NAME	The given name for the occurrence or deposit.
PROVINCE	The major region political subdivision of the country
TEC-SETTING	The major regional tectonic setting of the deposit or occurrence.
TYPE	Geological type of deposit or occurrence. See Annex IV for explanation.
STATUS	Deposit Status is as follows:

Anomaly

An anomaly is a local feature distinguishable in a geophysical or geochemical survey over a larger area. It may or may not be associated with a commercially valuable mineral deposit.

Occurrence

An occurrence is a site at which uranium mineralization has been identified but for which no investigation has been made to determine the extent of mineralization.

Prospect

A prospect is an occurrence which has undergone investigation at the trenching or drilling level but for which the size or value has not been established.

Dev. Prospect

A developed prospect is an occurrence which has undergone or is undergoing intensive study for the purpose of determining the extent and charateristics of the deposit but for which an economic evaluation has not yet been made.

Sub-economic Deposit

A sub-economic deposit is a developed prospect that has been evaluated as not economically recoverable with current technology. That is, it is a deposit with Reasonably Assured Resources recoverable at costs greater than US$ 130/kg U.

Data Field	Explanation

STATUS (continued)

Economic Deposit

An economic deposit is a developed prospect that is identified as an economically recoverable ore deposit with current technology. That is, it has Reasonable Assured Resources recoverable at costs of US$ 130/kg U or less. It may also be a deposit undergoing active development prior to becoming a producer.

Mine

A mine is a deposit from which ore is currently being recovered.

Depleted Mine

A depleted mine is, a mine-out or depleted ore deposit with insufficient Reasonably Assured Resources recoverable at US$ 130/kg U or less to support further production.

Inactive Mine

An inactive mine is a closed mine with remaining Reasonably Assured Resources recoverable at US$ 130/kg U or less.

SZ — The deposit size is classified as follows:

A-	0 - 10	Tonnes U
B-	10 - 100	Tonnes U
C-	100 - 1,000	Tonnes U
D-	1,000 - 10,000	Tonnes U
E-	> 10,000	Tonnes U

For South America

Data collected from the PREU (Programa Regional Evaluacion Uranifera) Study (reference # 390) had the following size categories:

0 - 200	Tonnes U	Assigned Class "B"
200 - 1,000	Tonnes U	Assigned Class "C"
1,000 - 10,000	Tonnes U	Assigned Class "D"

HOST ROCK — The principal host rock type for the occurrence. See the abreviations list in Annex I.

HOST AGE — The age of the host rock. See abreviations for age in Annex I.

REFERENCES — Contains reference numbers to bibliography. Refer to Table IV for the reference.

TABLE 2 Uranium Occurrences in Canada

The information contained in Table II was provided by the Geological Survey of Canada in computer readable form. This following describes the data fields contained in the Canadian data:

Data Field	Explanation
MAP-CODE	The map-code is a seven digit code prefixed by "CAN-" and followed by a three digit ascession number (e.g. CAN-123).
DEPOSIT NAME	The given name for the occurrence or deposit.
GSC NUM	A unique code assigned by the Gelogical Survey of Canada.
NTS	The map sheet number in which the occurrence or deposit is located expressed in the Canadian National Topographic System.
TEC-SETTING	Major regional tectonic setting.
TYPE	Geologic type of deposit or occurrence. See Annex IV for explanation.
STATUS	Deposit Status is as follows:

Occurrence

An occurrence is a site at which uranium mineralization has been identified but for which no investigation has been made to determine the extent of mineralization.

Prospect

A prospect is an occurrence which has undergone investigation at a trenching or drilling level but for which the size or value has not been established.

Dev. Prospect

A developed prospect is an occurrence which has undergone or is undergoing intensive study for the purpose of determining the extent and charateristics of the deposit but for which an economic evaluation has not yet been made.

Res. Known

A deposit or occurrence for which the resource has been estimated.

Mine

A mine is a deposit from which ore is currently being recovered.

Depleted Mine

A mine-out or depleted ore deposit with insufficient Reasonable Assured Resources less than US$ 130/kg U to consider further production.

Data Field	Explanation
STATUS	(Continued)

Inactive Mine

A closed mine with remaining Reasonably Resources recoverable at US$ 130/kg U or less.

SZ (SIZE)	Size of uanium occurrences or deposits is as follows:
	U- Not evaluated
	1- 0 - 100 Tonnes U
	2- 100 - 1,000 Tonnes U
	3- 1,000 - 10,000 Tonnes U
	4- > 10,000 Tonnes U
DEPOSIT COMMENTS	This is a brief text description of the occurrence or deposit. See abreviations in Annex I.
REF	Contains reference numbers for the bibliography. Refer to Table IV for the reference.

TABLE 3 Uranium Occurrences in the United States of America

Data recorded for the USA was largely derived from the U.S. Department of Energy National Uranium Resource Evaluation (NURE) programme, the Uranium Occurrence Reports (UORs). The NURE programme evaluated the uranium resource potential of 152 1°x 2° quadrangles in the continental Unites States and Alaska. These reports make up the bulk of the data from the USA. Annex XI shows the location of the evaluated quadrangles in the United States of America. Each published quadrangle folio contained an appendix of the UORs on microfiche.

The data were recorded in a text-oriented database using the CDS/ISIS package (Computerized Documentation Service / Intergrated Set of Information Systems) and an extract of the information provided for this publication. The data are organized by state but listed with the quadrangle name and associated occurrence number (e.g. TRINIDAD 0012).

Data Field	Explanation
MAP-CODE	The map-code is a 7 digit code prefixed by "US-" followed by a four digit ascession number (e.g. US-0123) and is used to as a reference to the maps. A unique map code is assigned for each occurrence or deposit
DEPOSIT NAME	Assigned Deposit name
DISTRICT or QUAD	If the occurrence is from the NURE programme, the quadrangle name and occurrence number is a unique combination (e.g. Millett 0021). If only a district name is printed, there is no number following the name.
TEC-SETTING	The tectonic setting of the occurrence.
TYPE	The deposit type is a numeric code taken from Annex V.
STATUS	The deposit status for the occurrences and deposits in the United States may be slightly misleading. The terms refer to the development status of the property independent of the commodity involved. Therefore, in a number of cases, the term producer may not refer to a producer of uranium although the great majority of the properties contained in this Atlas have produced uranium. The history of uranium production in the United States from its earliest days has seen the development and production of many very small

STATUS (Continued)

deposits such as those on the Colorado plateau. This is reflected by the information contained in the Atlas. Status is classified as follows:

UNKNOWN

The status for the occurrence is unknown.

(1)Occurrence

An occurrence is a site at which uranium mineralization has been identified but for which no investigation has been made to determine the extent of mineralization.

(2)Prospect

A prospect is an occurrence which has undergone cursory investigation at the trenching or drilling level but for which the size or value has not been established.

(3)Dev. Prospect

A developed prospect is an occurrence which has undergone or is undergoing intensive study for the purpose of determining the extent and charateristics of the deposit but for which an economic evaluation has not yet been made.

(4)Producer

A Producer is any deposit which has undergone exploitation for any commodity including uranium.

SZ (SIZE) The deposit size is classified as follows in pounds U3O8:

A-	0 - 20,000	(0 - 10	Tons)*
B-	20,000 - 200,000	(10 - 100	Tons)
C-	200,000 - 2 million	(100 - 1,000	Tons)
D-	2 million - 20 million	(1,000 - 10,000	Tons)
E-	More than 20 million	(> 10,000	Tons)

Because the estimate of size is an order-of-magnitude approximation of the true deposit size, errors resulting from using the above size classes as metric tonnes U are considered small, the maximum error in any class being 26%, and maps are presented in ranges of metric tonnes U.

HOST ROCK Primary host rock type. See abreviations in Annex I.

HOST AGE Age of the host rock. See abreviations in Annex I.

REFERENCES Contains reference numbers to bibliography. Refer to Table IV for the reference.

---

* Short Tons U3O8

TABLES 4 & 5: INTURGEO Bibliographic References

Tables 4 and 5 contain all references used in the preparation of INTURGEO with the exception of references used in the USDOE NURE programme. For these occurrences, a single reference is made to the two report series of the USDOE which are PGJ/F- and GJQ- (Reference #3002). These reports series are available from the USDOE Library in Grand Junction, Colorado. The reference to the NURE occurrences is an INTURGEO database compilation of all of the UOR's described in these reports. All the references used to compile the UOR's are too numerous to be published here and number about 3,000 additional references. These are available for each UOR in the INTURGEO/MicroISIS system.

Table 4 contains the INTURGEO references in ascending order by reference number. Table 5 contains the same references sorted by author and title. These 990 references include almost all of the IAEA papers published on the subject of uranium deposit geology as well as many unpublished papers from IAEA Member States. Annex XII contains all organization abbreviations used in the bibliography.

Annex IV

DEPOSIT CLASSIFICATION FOR THE WORLD*

Deposit types for Tables 1 and 2

The following abbreviations define deposit and occurrence types associated with Tables 1 and 2. The letter associated with each class identifies the deposit types within the pie diagrams for each map:

MPCD	Disseminated deposits in magmatic or pegmatitics rocks
MSOMA	Metasomatic type
UNCONF	Precambrian unconformity related
PHOS	Phosphorites
PLACER	Stream or beach placers
QTZPEB	Precambrian Quartz Pebble conglomerate
SS	Sandstone

ADABAS/INTURGEO DATABASE MODEL

PHYSICAL FILE STRUCTURE

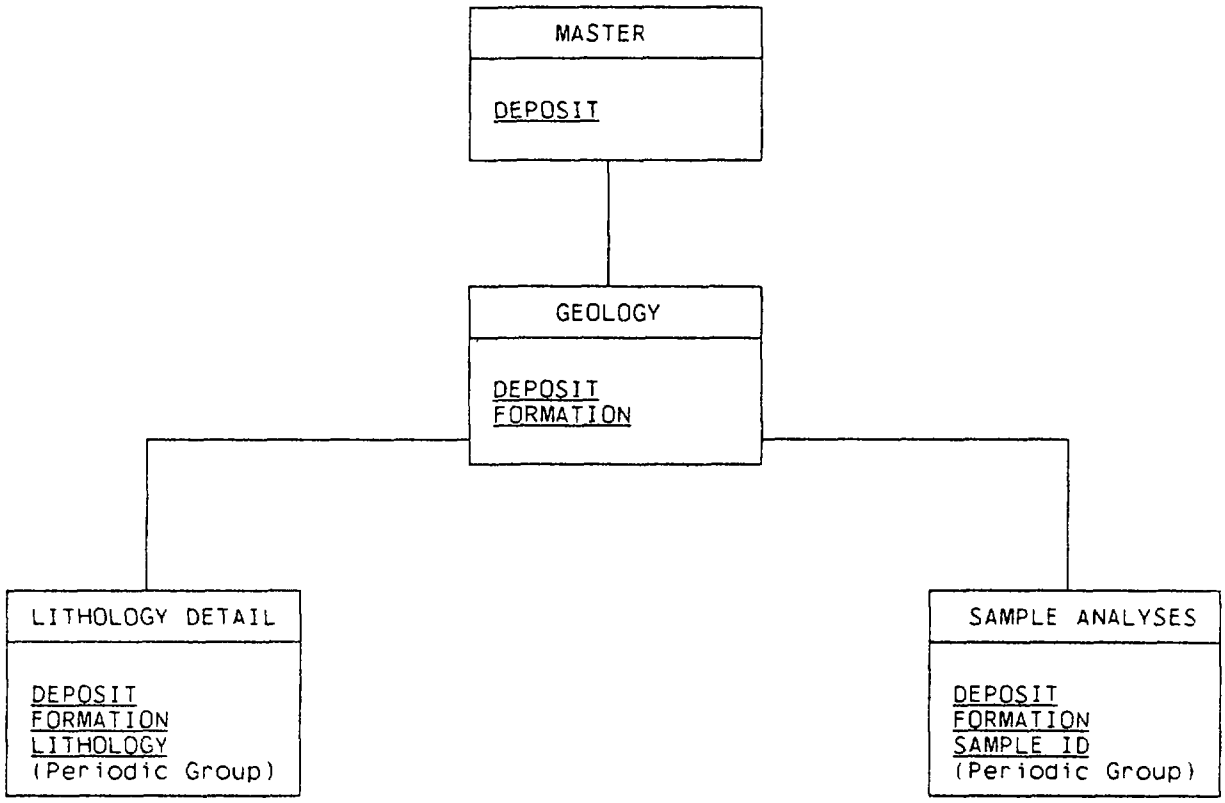

Primary keys for each file are indicated in each box. Refer to the Logical Structure diagragms for the GEOLOGY file and the RES-PRODUCTION file for an explanation of the logical file structures.

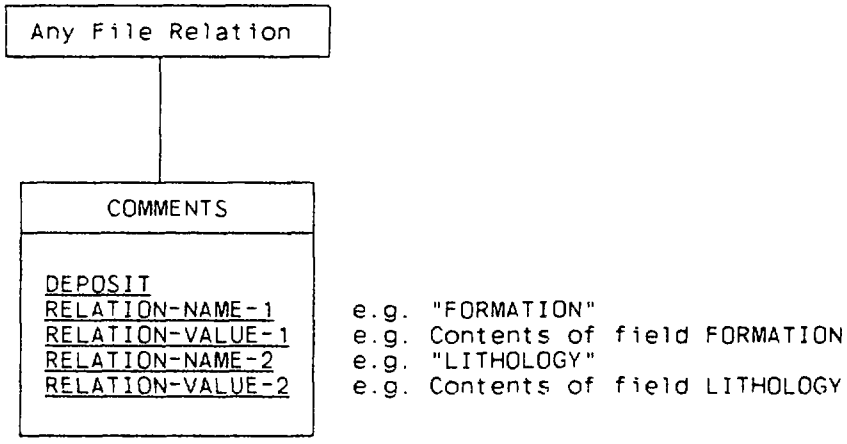

LOGICAL STRUCTURE FOR MASTER FILE

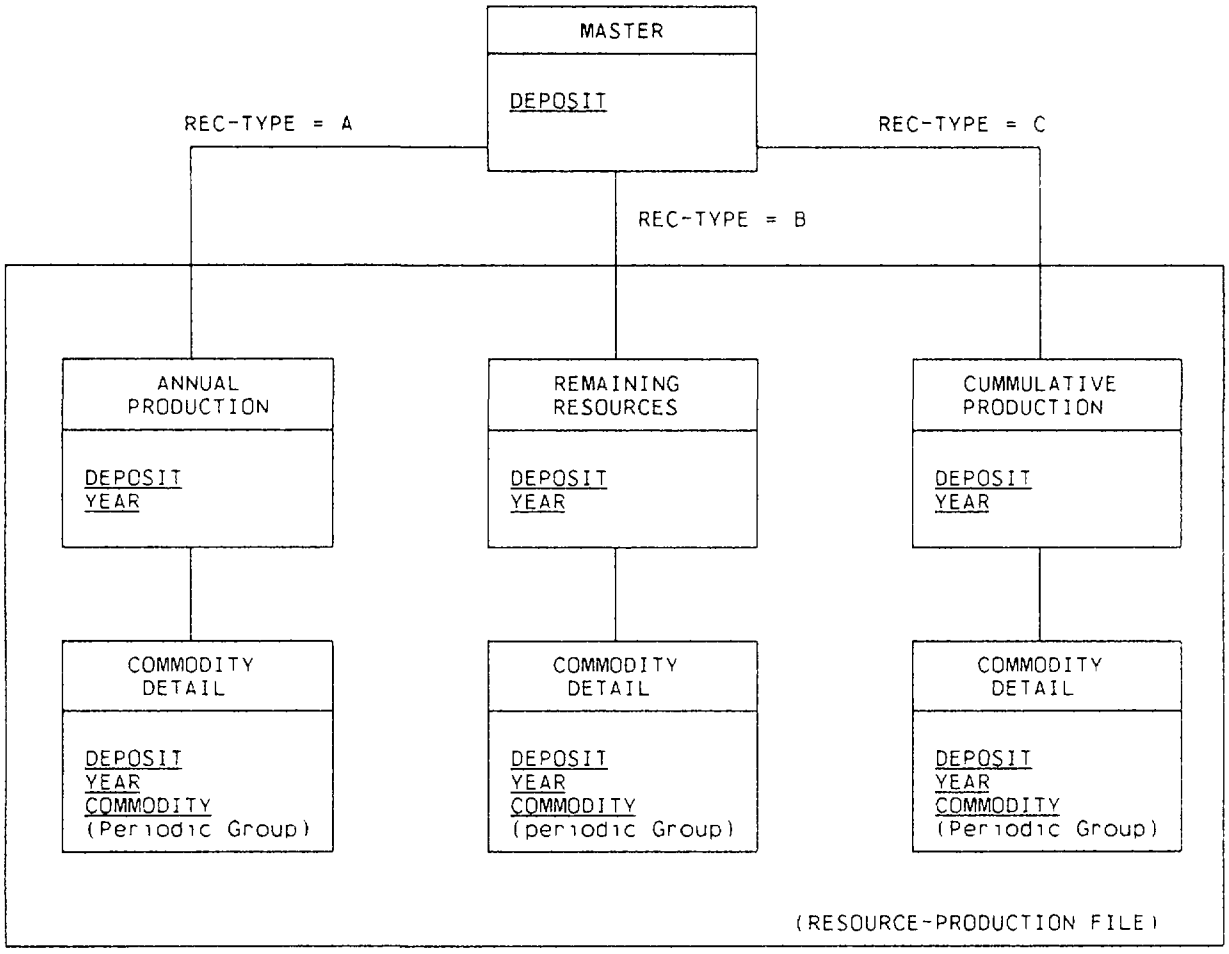

The MASTER file contains six periodic groups which are represented above.

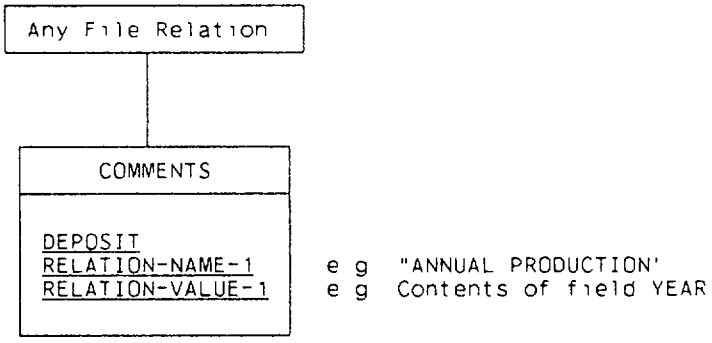

LOGICAL STRUCTURE FOR GEOLOGY FILE

LOGICAL STRUCTURE FOR RESOURCE-PRODUCTION FILE

The Resource-Production file is used for three purposes depending on the value of the record-type Because the structure of the data contained in each type of record is very similar it was easier to implement the above structure using one physical file

DEPOSIT SUMMARY

The Itataia deposit is located in the central Ceara uranium-phosphate (U-P) district and was discovered during the course of a carborne radiometric survey in 1975. The central Ceara U-P district lies in two tectonic units known as the Jaguaribean fold belt, and the Santa Quiteria massif This fold belt is bordered on the NE and southwest by the Santa Quiteria massif, the limits of which are, in part, marked by two large transcurrent faults known as the Groaira and Itatira faults. The Jaguaribean fold belt consists of highly folded metasediments which overlie the granitic basement. these sediments include carbonates, arkoses and occasional beds of marl which have been metamorphosed to the grade of the amphibolite facies. The rocks are attributed to the Caico group (upper proterozoic). The folding within the belt has been attributed to differential movement between the stable blocks of the Santa Quiteria massif the primitive rocks of the Santa Quiteria massif consisted of sedimentary, volcanic and possibly basic rocks. these have been subjected to a high degree of sialization and have been transformed almost completely by the granitization of the crust about 2,000 MY ago. the rocks were rejuvenated 1,300 MY ago, and again at the end of the Brazilian cycle, 540 MY ago. Of considerable interest are the post-orogenic granites (450 - 500 MY) which have been emplaced preferentially in the Santa Quiteria massif while bodies of reduced size occur in the Jaguaribean fold belt. The emplacement of these granites was controlled by extensive regional faulting, and especially those faults formed by compressional release. Some of these intrusive granites possess high values of U308 (10 to 100 ppm) as well as concentrations of P205 (0.65 to 1.3%) which exceed those normally found in granites. (From Marques, 1981)

LOCATION

The Itataia deposit is located in the U-P district of the central part of the state of Ceara, about 45 km SE of the town of Santa Quiteria, and about 170 km southwest of Fortaleza. The surrounding countryside is hilly and the exposure is good. (From Marques, 1981)

REMAINING RESOURCES 1980

Present RAR reserves for the Itataia deposit are 83,000 t U308 and EAR reserves of 39,500 t. The P205 reserves exceed 13,400,000 t. The U308 and P205 contents of the different ores are: collophanite: 0 15 to 0.9% U308 and 20 to 38% P205 marble (stockworks) and gneiss 0 04 to 0 1% U308 and 5 to 15% P205 (From Marques, 1981)

REGIONAL GEOLOGY

The Itataia district is situated in the uranium-phosphate district of the central part of the state of Ceara. The district lies between two tectonic units known as the Jaguaribean fold belt and the Santa Quiteria massif The regional rocks are precambrian paragneisses in addition to a large carbonate lens at least 10km in length Both the gneisses and the carbonates are cut by several granitic and pegmatitic apophyses in addition to a small granite cupola These intrusives have been affected regionally by deuteric processes (NEA/IAEA Redbook draft - 11Sep1981) The mineralization of the Itataia deposit has been described fully by Angeiras et al (1978) and Forman & Angeiras (1979) who considered that the mineralization had evolved at least during four episodes or stages 1 Intense hydraulic fracturing of the country rocks, 2 Intense magmatic activity of a deuteric nature, 3 Local deformation of the country rocks accompanied by the formation of "episyenites", 4 Extensive deposition of cryptocrystalline hidroxyapatite and, in addition, a widespread replacement of the calcite and feldspar by phosphate in the marbles and 'episyenites' respectively (From Marques, 1981)

HOST-ROCK GEOLOGY

Two ore types have been recognized The first one consists of uniform masses of collophane and the second one of collophane veinlet and stockwork in marbles in 'episyenites' in gneisses as well as impregnations in these rocks Uranium occurs in the cryptocrystalline hydroxy-apatite which is also of commercial interest as phosphate ore The rock in which this mineral occurs 80% has been refered to as collophanite The uranium is evenly distributed in this and two genetic interpretations have been proposed concerning the nature of the uranium in the collophane. The first is that calcium has been isomorphously replaced by uranium in the collophane structure The second view holds that the uranium is associated with finely dispersed oxides or that it has been absorbed by the collophane However, it is important to note that no discrete uranium species has been found as yet (From Marques, 1981)

MINERALOGY

Barretto (1982) describes the Itataia type of mineralization as being masses of collophane, veinlets and stockworks of collophane and impregnations in gneisses and feldspathic episyenite

FAVORABILITY CRITERIA

The unusual uranium-phosphorous mineralization at Itataia bears similarities with the uranium-rich apatite deposits of the USSR as described by Kazansky and Laverov (1977) The uranium is associated with cryptocrystalline apatite and other features in common include albitization, chloritization, dequartzification as well as the presence of trace elements (y, la, zr etc) The studies in the area are underway and presently NUCLEBRAS started building up a pilot plant for 50 t U3O8/y and 5,000 t P2O5/y Besides the deposits at Itataia, there are several very promising prospects in the neighbourhood of the central Ceara uranium-phosphate district These are known as Aquiri, Taperuaba, Mufumbo, etc However, it is important to stress that the mineralization these prospects occurs as disseminations in "feldspathic episyenites" which are characterized by intense albitization, chloritization, hematitization and dequartzification The uranium is present in well formed crystals of fluor-apatite which occurs as fillings in vuggs caused by the dequartzification These prospects are presently being studied in detail This type of mineralization is now known to occur all over north-eastern Brazil and it is believed that this was one of the most important metallogenetic events for uranium in south america It is thought to be time related to the late and post orogenic granites which were intruded towards the end of the Brazilian cycle (540 to 460 MY) (Angeiras et al, 1978). (From Marques, 1981)

Tectonic Setting N15 < Mobile belt >

Major Regional Structures N5 < The mine is located along the SE edge of the McDermitt Caldera, a circular Miocene volcanic subsidence feature about 40 km in diameter. The Kings River Valley, a major NNW basin and range valley is just W. >

Local Structures N70 < The uraniferous vein is apparently along a major ring fracture bounding the caldera. This fracture can be traced for at least four mi to the N. >

Host-FM. Name U1 < > Member U2 < >

Host Rock K1 < M I O ½ (Age) Dark gray rhyolitic ash flow tuff with sparse (Rock type, texture, composition, color, alteration, attitude, geometry, structure, etc.)

crystals, grey aphanitic rhyolite(?), and hornblende-biotite granodiorite comprise the footwall of the breccia vein. The hanging wall consists of biotite rhyolite breccia with grey, nearly aphanitic intrusive(?) rhyolite. >

Host-Rock Environment U3 < Volcanic-pyroclastic, possibly shallow intrusive. > (Sed. dep. environ., metamorphic facies, ign. environ.)

Comments on Associated Rocks U4 < In the hanging wall above the mine is a sequence of biotitic rhyolite to quartz latite ash flow tuffs nearly 500 ft thick. Above this lies one or more peralkaline ash flows comprising up to 700 ft of section. Intermediate* >

Ore Minerals C30 < Autunite, torbernite, and late-stage metamict zircon which contains anomalous amounts of uranium. >

Gangue Minerals K4 < Quartz, pyrite, limonite, fluorite, arsenopyrite, and galena. >

URANIUM-OCCURRENCE REPORT

Quad Name Vya

Deposit No. 6

Alteration N75 < Silicic, argillic, and potassic (potash feldspar and sericite).

>

Reductants U5 < Sulfide was probably deposited during the same hydrothermal event which produced the uranium enrichment, and was not important as a reductant.

>

Analytical Data (General) C43 < Select samples contain up to 0.25 % U_3O_8 and 0.39% eU. The breccia vein contains an average of 0.04% U_3O_8. Altered country rock is enriched, with chip samples representing large volumes of rock containing* >

Radiometric Data (General) U6 < Bkg. in country rock is 200 to 300 cps (60-90 UR). (No. times background and dimensions) The breccia vein ranges between 4000 and 20000+cps (1200-5800+ UR) for a distance of about 450 ft. Altered rock adjacent to the vein ranges between 500 and 4000 >

Ore Controls K5 < The breccia vein is controlled by a moderate to high-angle fault which is thought to be part of the McDermitt Caldera ring fracture system. According to Rytuba and Glanzman (1978), the Moonlight Mine is at the junction of the Calavera and Jordan Meadow Calderas. Our mapping (see p. 7) shows little or no stratigraphic offset across Calavera Canyon, which indicates either that the Calavera Caldera ring fracture zone is mislocated by Rytuba and Glanzman, or that the Calavera Caldera does not exist. We were also unable to locate the southern * >

Deposit Class C40 < Volcanogenic > Class No. U7 < | | | >

Comments on Geology N85 < Shallow hydrothermal. Rytuba and Glanzman (1978) reported that fluid inclusions indicate a deposition temperature of 330° C and that stratigraphic evidence provides for a depth of formation of about 800 m.

URANIUM-OCCURRENCE REPORT

Quad Name Vya

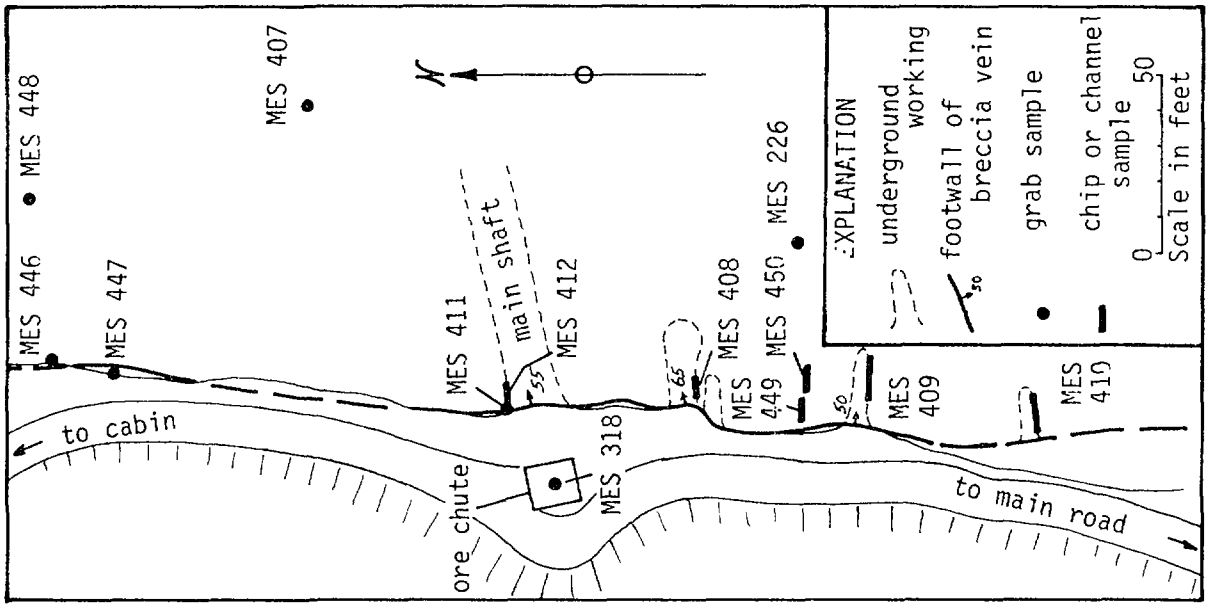

Deposit No. 6

Continuation from p. 1-5:

Label

A 83 < valley and drive about 6 mi. Turn right onto a dirt road and drive 1.5 mi to the mine.

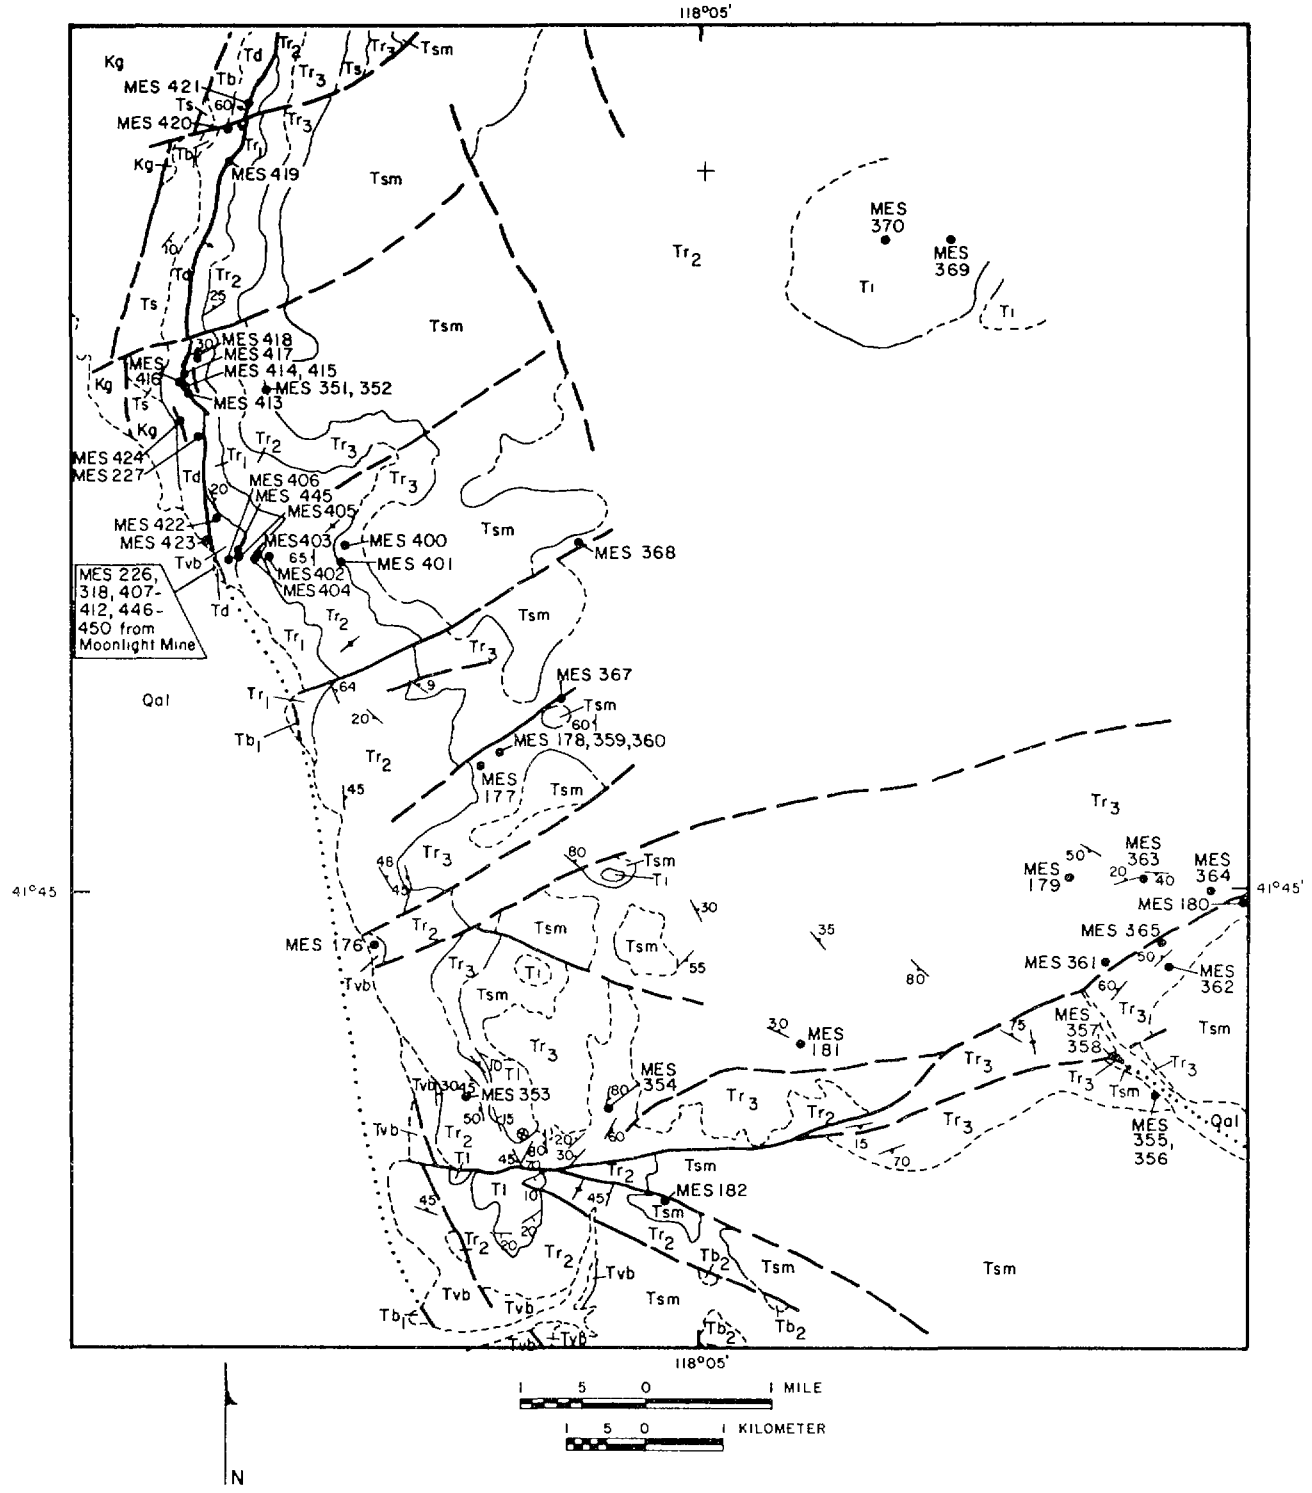

M 40 A possible extension of the vein is about 1200 ft NNW of the mine, which suggests a total length of over 1600 ft.

U 4 to rhyolite flows and tuffs comprising 2000 ft of section overlie the peralkaline ash flows, and are capped by a sequence of peralkaline rhyolite ash flows at least 600 ft thick which form the plateau-like top of the Montana Mtns east of the mine. Caldera moat sediments overlie these ash flows on the top of the Montana Mtns.

C 43 up to 77 ppm U_3O_8. All select samples of ore have high Ag, As, Mo, and Sb; most have high Ba, Cu, F, Hg, P, Sn, W, and Zr. A select sample from a fluorite-bearing breccia occurrence about 1200 ft NNW of the mine (spl. MES 423) contains 0.17% U_3O_8 and has trace element contents similar to those of select samples from the mine.

U 6 cps (150-1200 UR).

K 5 ring fracture zone of the Jordan Meadow Caldera. However, Calavera Canyon lies along a distinct photolinear, which may represent one of a number of NW faults (see p. 7) several of which do control uranium occurrences elsewhere. Intersections of ring fractures with cross-cutting fractures may be an important ore control at the Moonlight Mine and elsewhere in the McDermitt Caldera.

TAG - The ISIS field number.
CRIB-CODE - Field code assigned by the U.S. Geological Survey for the CRIB data base.
MULT- If "M" then the field is a multiple occurrence field. If "PM" then the associated fields are a periodic group having multiple subfields.
TYPE- "A" - Alphanumeric field
"N" - Numeric field

61-M40-LENGTH  : 450 ft
63-M50-WIDTH   : 9 ft
65-M60-THICK   : 240 ft
67-M70-STRIKE  : N-S to N15W
68-M80-DIP     : 55 to 60E
69-N15-TEC.SET : Mobile belt
70-N5-MAJ.STR  : The mine is located along the SE edge of the McDermitt. The Kings River
                 Valley, a major NNW basin and range valley is just W.
71-N70-LOC.STR : The uraniferous vein is apparently along a major ring fracture bounding
                 the caldera. This fracture can be traced for at least four mi to the N.
74-K1-AGE HOST : MIO
75-K1-HOST RXS : Dark gray rhyolitic ash flow tuff with sparse crystals, grey aphanitic
                 rhyolite (?), and hornblende-biotite granodiorite comprise the footwall
                 of the breccia vein. The hanging wall consists of biotite ryholite
                 breccia with grey, nearly aphanitic intrusive (?) rhyolite.
76-U3-HOST ENV : Volcanic-pyroclastic, possibly shallow intrusive.
77-U4-ASS. RXS : In the hanging wall above the mine is a sequence of biotitic ryholite to
                 quartz latite ash flow tuffs nearly 500 ft thick. Above this lies one or
                 more peralkaline ash flows comprising up to 700 ft of section.
                 Intermediate to rhyolite flows and tuffs comprising 2000 ft of section
                 overlie the peralkaline ash flows, and are capped by a sequence of
                 peralkaline rhyolite ash flows at least 600 ft thick which form the
                 plateau-like top of the Montana Mtns. east of the mine. Caldera moat
                 sediments overlie these ash flows on the top of the Montana Mtns.
78-C30-ORE MIN : Autunite, torbernite, and late-stage metamict zircon which contains
                 anomalous amounts of uranium.
80-K4-GANGUE   : Quartz, pyrite, limonite, fluorite, arsenopyrite, and galena.
82-N75-ALTER   : Silicic, argillic, and potassic (potash feldspar and sericite).
83-U5-REDUCT   : Sulfide was probably deposited during the same hydrothermal event which
                 produced the uranium enrichment, and was not important as a reductant.
84-C43-CHEM    : Select samples contain up to 0.25% U3O8 and 0.39% eU. The breccia vein
                 contains an average of 0.04% U3O8. Altered country rock is enriched,
                 with chip samples representing large volumes of rock containing up to 77
```

ppm U3O8. All select samples of ore have high Ag, As, Mo, and Sb, most have high Ba, Cu, F, Hg, P, Sn, W, and Zr. A select sample from a fluorite-bearing breccia occurrence about 1200 ft NNw of the mine (spl. MES 423) contains 0.17% U3O8 and has trace element contents similar to those of the select samples from the mine.

85-U6-R/M DATA : Bkg. in country rock is 200 to 300 cps (60-90 UR). The breccia vein ranges between 4000 and 20000+cps (1200-5800+UR) for a distance of about 450 ft. Altered rock adjacent to the vein ranges between 500 and 4000 cps (150-1200 UR).

86-K5-CONTROLS : The breccia vein is controlled by a moderate to high-angle fault which is thought to be part of the McDermitt Caldera ring fracture system According to Rytuba and Glanzman (1978), the Moonlight Mine is at the junction of the Calavera and Jordan Meadow Calderas Our mapping shows little or no stratigraphic offset across Calavera Canyon, which indicates either that the Calavera Caldera ring fracture zone is mislocated by Rytuba and Glanzman, or that the Calavera Caldera does not exist. We were also unable to locate the southern ring fracture zone of the Jordan Meadow Caldera. However, Calavera Canyon lies along a distinct photolinear, which may represent one of a number of NW faults several of which do control uranium occurrences elsewhere Intersections of ring fractures with cross-cutting fractures may be an important ore control at the Moonlight Mine and elsewhere in the McDermitt Caldera.

87-C4O-CLASS : Volcanogenic

89-N85-COMMENT : Shallow hydrothermal. Rytuba and Glanzman (1978) reported that fluid inclusions indicate a deposition temperature of 330C and that stratigraphic evidence provides for a depth of formation of about 800 m.

90-SAMPLE	DESCRIPTION	LAB ANALYSIS
MES-226	Representative grab spl. of rhyolite dike (?) rock	128 ppm eU
MES-318	Select grab spl of unoxidized ore from dump	780 ppm U3O8

ABBREVIATIONS USED IN THE BIBLIOGRAPHY

(Tables 4 and 5)

AAEC	Australian Atomic Energy Commission
AAPG	American Association of Petroleum Geologists
AEE	Atomic Energy Establishment (Egypt)
BRGM	Bureau de Reserches Geologiques et Minieres
CCHEN	Comision Chilena de Energia Nuclear
CEA	Commissariat a l'Energie Atomique
CEEA	Comision Ecuatoriana de Energia Atomica
CIEN	Comision Interamericana de Energia Nuclear
CNEA	Comision Nacional de Energia Atomica (Argentina)
CNEN	Comision Nacional de Energia Nuclear (Mexico)
CNEN	Comissao Nacional de Energia Nuclear (Brazil)
COBOEN	Comision Boliviana de Energia Nuclear
CODESA	Corporacion Costarricense de Desarollo S.A.
COGEMA	Compagnie Generale des Matiers Nucleares
DNGM	Direction Nationale de la Geologie et des Mines (Mali)
ENEC	Ethiopian Nuclear Energy Commision
ENU	Empresa Nacional de Uranio (Portugal)
GAEC	Greece Atomic Energy Commission
IAEA	International Atomic Energy Agency
IMM	Institute of Mining and Metallurgy
IPEN	Instituto Peruano de Energia Nuclear
IUREP	International Uranium Resource Evaluation Programme
JCEA	Junta de Control de Energia Atomica (Peru)
KIER	Korea Institute of Energy and Resources
KIGAM	Korea Institute of Geology and Mining
NEA(OECD)	Nuclear Energy Agency (see OECD)
NUCLAM	NUCLEBRAS - Urangesellschaft Joint Venture
NUCLEBRAS	Empresas Nucleares Brasileiras S.A.
OECD	Organization for Economic Co-operation and Development
OIEA	Organismo Internacional de Energia Atomica (IAEA)
ONM	L'Office National des Mines (Tunesia)
PNC	Power Reactor and Nuclear Fuel Development Corporation
PNUD	Programa de las Naciones Unidas para el Desarolla (UNDP)
PNUD	Programme des Nations Unies pour le Developpement (UNDP)
PREU	Programa Regional Evaluacion Areas Uraniferas
SPE	Company with UNDP
UNDP	United Nations Development Programme
USAEC	United States Atomic Energy Commission
USBM	United States Bureau of Mines
USDOE	United States Department of Energy
USERDA	United States Energy Research and Development Administration
USGS	United States Geological Survey
